Background: Anaphylaxis is a serious, potentially life-threatening condition. Adequate preparation for anaphylaxis management is imperative for school personnel. This descriptive pilot study assessed preparedness of US schools to manage anaphylactic reactions.

Methods: An exploratory, cross-sectional, web-based, pilot survey assessed the occurrence and characteristics of anaphylactic events, as well as training provided to school personnel for the recognition and treatment of anaphylaxis. Eligible US schools were participants in the EpiPen4Schools[®] program during the 2013–2014 school year. EpiPen4Schools provides EpiPen[®] (epinephrine injection) Auto-Injectors and training materials to qualifying US schools. Survey data were parsed by US Census Bureau region and state and were evaluated using descriptive statistics.

Results: Schools from all 50 states and the District of Columbia participated in the survey (N=6,019). Among schools that provided information on anaphylactic events, 11% (607/5,683) reported the occurrence of one or more events, with significant variability in incidence across census regions and among states. A total of 5,613 schools provided information regarding which staff members were trained to recognize the signs and symptoms of anaphylaxis. Thirty-six percent of schools (2,022/5,613) indicated that only the school nurse and select staff were trained in anaphylaxis recognition. The proportion of schools in which most or all school staff received such training differed by region/state (range, 13%–100%). A total of 5,578 schools provided information on which staff were permitted to administer epinephrine. The majority of schools (54%; 3,024/5,578) permitted only the school nurse and select staff to administer epinephrine, although percentages varied by region/state (range, 4%–100%).

Conclusion: Schools differed substantially in their preparedness to manage anaphylaxis, with significant disparities in staff training and permission to treat. Given the ramifications of delayed treatment, removing barriers to the recognition and treatment of anaphylactic events in schools is an important public health goal.

Keywords: anaphylaxis, epinephrine, epinephrine auto-injector, preparedness, school nurse, school staff training

Background

The prevention and management of anaphylaxis in the school setting is increasingly recognized as a public health concern as the incidence of food allergies, a major trigger for anaphylaxis, appears to be on the rise in children.¹ From 1997 to 2007, the prevalence of reported food allergy in the US increased by 18% in children <18 years of age.²

Unfortunately, many times the school is unaware that a child has a life-threatening allergy before the occurrence of an anaphylactic event.³ Likewise, it is not uncommon for a child to experience a first-time anaphylactic attack in the school setting.⁴

Often, children who experience an anaphylactic reaction do not receive epinephrine, the first-line treatment option, before presentation to the emergency department.^{5,6} Delay in the recognition and treatment of anaphylaxis has serious ramifications from hospitalization⁵ and biphasic reactions⁷ (ie, a reoccurrence of anaphylaxis symptoms hours after the index event) to death.^{8,9} Indeed, a majority of fatalities due to anaphylaxis that have been observed among adolescents and young adults have involved a lack of timely access to epinephrine.⁹ Hospitalization also has serious repercussions as it is disruptive to school attendance and daily activities and is a source of financial burden. In the US, hospitalizations for anaphylaxis are estimated to cost \$4,500 per event,¹⁰ and anaphylaxis is estimated to have total direct expenditures ranging from \$288 million to \$3.7 billion.¹¹ To prevent or mitigate these adverse sequelae, adequate training programs are needed to properly educate school personnel to recognize and treat anaphylactic reactions.

The results presented here from a pilot survey among US schools participating in the EpiPen4Schools[®] program (Mylan Specialty L.P., Canonsburg, PA, USA) describe the occurrence of anaphylactic reactions and the training and personnel resources available to manage these events. Evaluating these aspects of anaphylaxis management will allow for a better assessment of school preparedness to deal with these serious and potentially life-threatening events.

Methods

Data source

Eligible schools were participants in the EpiPen4Schools program, which provides EpiPen[®] (epinephrine injection) Auto-Injectors (Mylan Specialty L.P.) and training materials to qualifying public and private kindergarten, elementary, middle, and high schools in the US. Participating schools received two EpiPen Auto-Injector 2-packs, two EpiPen Jr[®] Auto-Injector 2-packs, or one of each 2-pack free of charge. Of the >40,000 schools enrolled in the program, 32,387 schools had available contact information and were invited to participate in the survey.

The 15-question, web-based survey was to be completed by the person best qualified to provide information on anaphylactic events and preparedness, which was most often the school nurse.¹² Responses were limited to events that occurred during the 2013–2014 academic school year. A total

of 6,019 surveys were received between May 21, 2014 and July 9, 2014. Study design and survey methodology have been previously described in greater detail.¹²

Data analysis

Descriptive statistics were used to report the characteristics of participating schools (eg, census region, state), anaphylactic events, and staff training. Statistics were unweighted and, therefore, did not account for potential variation in individual school populations. Most questions included a count of missing data, as respondents were not required to answer every question. Therefore, percentages calculated for the descriptive statistics were derived using the total number of responses per question.

Ethics

The study was submitted to the RTI institutional review board (IRB) for approval, which determined that the research activity did not constitute research involving human subjects as defined by the US Code of Federal Regulations (45 CFR 46.102). The approval of these activities by the RTI IRB was not necessary; therefore, an exemption was granted.

Results

Respondents

The number of schools that enrolled in the EpiPen4Schools program varied by region and state, with the largest number of participating schools in the Northeast and the greatest single-state participation rate in New York (Table 1). Individual state survey participation rates ranged from 1% to 52%. There was no apparent association between the number of schools within a state that enrolled in the EpiPen4Schools program and percentage of schools that responded to the survey. However, survey participation rates were the lowest among the largest school districts and, in some cases, large districts were unable to participate at all because of requirements for research approval that could not be completed within the time frame for the study.

Anaphylactic events

Of the 6,019 schools that participated in the survey, 5,683 provided information on the occurrence of anaphylactic events, with 607 (11%) reporting that one or more anaphylactic events occurred during the 2013–2014 school year. A total of 919 events were described.¹² On a state-by-state basis, the number of anaphylactic events ranged from no events to a high of 103 events. When calculating the mean number of anaphylactic events per school (ie, number of anaphylactic events in a given

state divided by number of responding schools in that state), the values ranged from 0 to 0.29 (Table 2).

School staff trained to recognize anaphylaxis

Of the 6,019 schools that participated in the survey, 5,613 schools (93%) provided information regarding staff members who were trained to recognize anaphylaxis. In response to the question, “Who in your school is trained to recognize the signs and symptoms of anaphylaxis?”, the most common answer (reported by 36% of schools that provided data [2,022/5,613]) was that only the school nurse and select staff were trained (Figure 1A). Less than a third of schools (1,730/5,613) trained all staff, and 29% (1,621/5,613) trained most staff in anaphylaxis recognition.

When analyzed by state, the percentage of schools that trained most or all staff in anaphylaxis recognition was highly variable (Table 2). All represented schools from Iowa, North Dakota, and Washington, as well as the District of Columbia, reported training most or all staff. However, most or all staff training rates as low as 13% were also observed.

School staff who were permitted to administer epinephrine

A total of 5,578 schools provided information on the types of staff who were permitted to administer epinephrine via an epinephrine auto-injector (EAI). The majority of schools (54%; 3,024/5,578) permitted the school nurse and select staff to administer epinephrine (Figure 1B). All or most staff were permitted to administer epinephrine in 38% of schools, and just 3% of schools limited EAI use to the school nurse or visiting state school nurse consultant (ie, a nurse who rotates among multiple schools to provide services as needed). Three percent of responding schools allowed both students and staff to administer epinephrine.

Regional and state data demonstrated a high level of diversity in the types of staff who were permitted to administer epinephrine (Table 2). In almost all cases, the proportion of schools that allowed most or all staff to administer epinephrine was lower than the proportion of schools that trained most or all staff to recognize anaphylaxis. There was no apparent correlation between most/all staff training levels and most/all staff administration levels. For example, the states listed above as

Notes: ^aThe number of anaphylactic events per school was calculated as the number of anaphylactic events in a given state divided by the number of responding schools in that state. ^bSchools training most or all staff to recognize signs of anaphylaxis. This proportion was calculated relative to the number of schools in the indicated state that responded to the survey question about staff training to recognize the symptoms of anaphylaxis, which may differ from the overall number of participating schools in that state. ^cSchools permitting most or all staff to treat anaphylaxis with an epinephrine auto-injector. This proportion was calculated relative to the number of schools in the indicated state that responded to the survey question about staff permission to treat anaphylaxis with an epinephrine auto-injector, which may differ from the overall number of participating schools in that state.

having 100% training for recognition of signs and symptoms for most or all staff had comparatively low levels (25%–38%) of permission for EAI administration by most or all staff. However, in general, states with a high proportion of schools in which most or all school staff were permitted to administer epinephrine had a high proportion of schools that trained most or all staff on anaphylaxis recognition. For example, the five states listed as having >65% permission for EAI administration by most or all staff (Alaska, Florida, Idaho, Montana, and Wyoming) also had relatively high rates of training for recognition of anaphylaxis signs and symptoms for most or all staff (67%–83%). (Note: the rate of permission was 100% for the District of Columbia, but there were only two schools in the District of Columbia that responded to the survey.)

Discussion

The results of this descriptive pilot study show that schools' preparedness for managing anaphylaxis varies substantially.

Training in the recognition of anaphylaxis predominantly included the school nurse and select staff, and regional/state proportions of schools in which most or all staff were trained ranged from 13% to 100%. In general, fewer staff were permitted to administer epinephrine than were trained to recognize anaphylaxis signs and symptoms. In the majority of cases (54%), only the school nurse and select staff members were allowed to administer epinephrine. On a regional/state basis, the proportion of schools in which most or all school staff were permitted to treat anaphylactic events with EAIs ranged from 0% to 100%.

Few studies have evaluated school staff training in anaphylaxis recognition, anaphylaxis management, or both. When such studies have been conducted, they have typically involved a geographically limited sample. For example, a recent survey of food allergy management readiness included 78 schools from southeastern Wisconsin. Forty nine of the schools (66%) reported that they provided staff training on anaphylaxis and epinephrine.¹³

Figure 1 School staff training and permission.

Note: Types of school staff **(A)** trained to recognize the signs and symptoms of anaphylaxis and **(B)** permitted to administer epinephrine using an epinephrine auto-injector.

By expanding training and the ability to treat anaphylaxis, schools are better able to provide a timely response and, hence, increase the potential for a more favorable outcome. Evaluations of pediatric emergency department records have shown that less than half of children presenting with anaphylaxis received treatment with epinephrine in the pre-hospital setting.^{5,6} One of these studies reported that 12% of the analyzed anaphylactic reactions occurred at school.⁶ Of those, 69% of children were administered epinephrine by the school nurse. With the increasingly limited number of full-time school nurses⁶ and the potential for events to occur during field trips, before/after school hours, or during

extracurricular activities,¹⁴ depending on a limited pool of trained responders may put children at risk.

Along with the need for adequate staff training, it is important for schools to stock epinephrine because of the risk of reactions in individuals without previously known life-threatening allergies³ and because children and adolescents with known risk factors often fail to carry an unexpired EAI¹⁵ or do not have ready access to an EAI.¹⁶ Additionally, the majority of individuals at high risk of anaphylaxis do not receive personal prescriptions for EAIs.¹⁷ In the EpiPen4Schools survey, 22% of reported anaphylactic events occurred in individuals with no known allergies.¹² The

majority of anaphylactic events (75%) reported were treated using EAI; of these events, 49% were treated with stock EpiPen Auto-Injectors from the EpiPen4Schools program.¹² Most of the events that were not treated with an EAI were instead treated with antihistamines.¹²

Most states have legislation in place that allows schools to stock epinephrine.¹⁸ Nine states – California, Delaware, Maryland, Michigan, Nebraska, Nevada, New Jersey, North Carolina, and Virginia – have legislation that requires schools to stock epinephrine.¹⁸ Nonetheless, in a survey of school nurses from California, where stocking epinephrine and administration training for unlicensed assistive personnel are permitted, only 13% reported that their school had a stock epinephrine program in place.¹⁹ Moreover, despite the large presence of children with known food allergies, only 43% of schools from a Houston, Texas, school district reported having a stock EAI.²⁰ Schools with lower socioeconomic status were less likely than schools with higher socioeconomic status to stock EAI. Most states have laws regarding students carrying and self-administering prescribed epinephrine.²¹ While typically allowed by law, special approval is usually required. Since only 3% of responding schools said they allowed both students and staff to administer epinephrine, this suggests that, in practice, self-administration of EAI by students may not be broadly permitted.

As a voluntary survey that was open to a subset of US schools (ie, those schools with a potentially higher allergy awareness information base as they were already participating in the EpiPen4Schools program), the interpretation of these results is subject to inherent limitations (eg, reporting bias, respondent recall, variance related to interpretation of meaning). In addition, survey results were not adjusted for potential confounding factors such as regional variations in the size of the student populations and types of schools. Future studies may benefit from deeper analyses of the details surrounding each event, including specifics of treatment administered, location of the event, and hospital transport and follow-up; demographic data such as race/ethnicity and sex may also be probed. Moreover, additional questions pertaining to the reasons for limited staff training or permission to treat, including regulations enacted by state or local governing bodies such as school boards, could provide greater insight into barriers that may prevent more extensive staff involvement in anaphylaxis management.

Conclusion

The risks and costs associated with anaphylaxis warrant that schools be prepared to act quickly both in the recognition of

an anaphylactic event and in its treatment. Broader training of school staff, expanded staff involvement in treatment, and ready availability of medication are necessary to achieve this goal. The extent to which US schools have met these criteria is highly variable, both among schools and regions/states. To provide the best possible outcomes for children, barriers to their timely care within the school setting need to be identified and resolved.
